trigger the development of a defence response which through the activity of the nociceptive system includes pain. If the noxious impact does not induce tissue damage the pain called nociceptive pain ceases within seconds after the impact is withdrawn. In contrast if tissue damage does occur a pain experience that usually persists until the injury is resolved and includes two major pathological sensory experiences: hypersensitivity to heat stimuli i.e. heat hyperalgesia and or hypersensitivity to mechanical stimuli i.e. mechanical allodynia develop. The cellular and molecular mechanisms underlying the development of nociceptive pain are fairly well understood. Our understanding of the development of pain associated with tissue injury has also significantly improved in the last decades. Hence two fundamental mechanisms: interactions between the nervous and immune systems both within and without the central nervous system and sensitization that is a use dependent increase in the sensitivity and activity of neurons involved in nociceptive processing have been identified being pivotal for the development of tissue injury associated pain. However important details of the cellular and molecular mechanisms which account for the development of the pathological sensory experiences and those experiences becoming persistent still await elucidation.
